1	Monoidal Category	

1.1 Symmetric Monoidal Category

Definition 1. A symmetric monoidal category (SMC), $(\mathbb{C}, \bullet, 1, \alpha, \lambda, \rho, \gamma)$, is a category \mathbb{C} equipped with a bifunctor $\bullet : \mathbb{C} \times \mathbb{C} \rightarrow \mathbb{C}$ with a neutral element 1 and natural isomorphisms α, λ, ρ , and γ :

1. $\alpha_{A,B,C} : A \bullet (B \bullet C) \xrightarrow{\sim} (A \bullet B) \bullet C$
2. $\lambda_A : 1 \bullet A \xrightarrow{\sim} A$
3. $\rho_A : A \bullet 1 \xrightarrow{\sim} A$
4. $\gamma_{A,B} : A \bullet B \xrightarrow{\sim} B \bullet A$

which make the following 'coherence' diagrams commute.

diagramshere

The following equality is also required to hold:

$$\lambda_1 = \rho_1 : 1 \bullet 1 \rightarrow 1$$

1.2 Symmetric Monoidal Closed Category

Definition 2. A symmetric monoidal closed category (SMCC), $(\mathbb{C}, \bullet, \multimap, 1, \alpha, \lambda, \rho, \gamma)$, is a SMC such that for all objects A in \mathbb{C} , the functor $- \otimes A$ has a specified right adjoint $A \multimap -$.

Let \mathbb{C} be a SMC $(\mathbb{C}, \bullet, 1, \alpha, \lambda, \rho, \gamma)$. A structure $\langle M \rangle$ in \mathbb{C} for a given signature S_g is specified by giving an object $\llbracket \sigma \rrbracket$ in \mathbb{C} for each type σ , and a morphism $\llbracket f \rrbracket : \llbracket \sigma_1 \rrbracket \bullet \dots \bullet \llbracket \sigma_n \rrbracket \rightarrow \llbracket \tau \rrbracket$ in \mathbb{C} for each function symbol $f : \sigma_1, \dots, \sigma_n \rightarrow \tau$. In the case where $n = 0$ then the structure assigns a morphism $\llbracket c \rrbracket : 1 \rightarrow \llbracket \tau \rrbracket$ to a constant $c : \tau$.

Given a context $\Gamma = [x_1 : \sigma_1, \dots, x_n : \sigma_n]$ we define $\llbracket \Gamma \rrbracket$ to be the product $\llbracket \sigma_1 \rrbracket \bullet \dots \bullet \llbracket \sigma_n \rrbracket$. We represent the empty context with the neutral element 1. We need to define the bracketing convention. It shall be assumed that the tensor product is left associative, i.e. $A_1 \bullet A_2 \bullet \dots \bullet A_n$ will be taken to mean $(\dots(A_1 \bullet A_2) \bullet \dots) \bullet A_n$. We find it useful to define two 'book-keeping' functions,

$$Split(\Gamma, \Delta) : \llbracket \Gamma, \Delta \rrbracket \rightarrow \llbracket \Gamma \rrbracket \bullet \llbracket \Delta \rrbracket$$

$$Split(\Gamma, \Delta) \stackrel{\text{def}}{=} \begin{cases} \lambda_{\Delta}^{-1} & \text{If } \Gamma \text{ empty} \\ \rho_{\Gamma}^{-1} & \text{If } \Delta \text{ empty} \\ id_{\Gamma \bullet A} & \text{If } \Delta = A \\ Split(\Gamma, \Delta') \bullet id_A; \alpha_{\Gamma, \Delta', A}^{-1} & \text{If } \Delta = \Delta', A \end{cases}$$

$$Join(\Gamma, \Delta) : \llbracket \Gamma, \Delta \rrbracket \rightarrow \llbracket \Gamma \rrbracket \bullet \llbracket \Delta \rrbracket$$

$$Join(\Gamma, \Delta) \stackrel{\text{def}}{=} \begin{cases} \lambda_{\Delta} & \text{If } \Gamma \text{ empty} \\ \rho_{\Gamma} & \text{If } \Delta \text{ empty} \\ id_{\Gamma \bullet A} & \text{If } \Delta = A \\ \alpha_{\Gamma, \Delta', A}; Join(\Gamma, \Delta') \bullet id_A & \text{If } \Delta = \Delta', A \end{cases}$$

We shall also refer to indexed variants of these; for example

$$Split_n(\Gamma_1, \dots, \Gamma_n) : \llbracket \Gamma_1, \dots, \Gamma_n \rrbracket \rightarrow \llbracket \Gamma_1 \rrbracket \bullet \dots \bullet \llbracket \Gamma_n \rrbracket$$

which is defined in the obvious way.

The semantics of a term in context is then specified by a structural induction on the term.

$$\llbracket x : \sigma \triangleright x : \sigma \rrbracket \stackrel{\text{def}}{=} id_\sigma$$

$$\llbracket \Gamma_1, \dots, \Gamma_n \triangleright f(M_1, \dots, M_n) : \tau \rrbracket \stackrel{\text{def}}{=} Split_n(\Gamma_1, \dots, \Gamma_n); \llbracket \Gamma_1 \triangleright M_1 : \sigma_1 \rrbracket \bullet \dots \bullet \llbracket \Gamma_n \triangleright M_n : \sigma_n \rrbracket; \llbracket f \rrbracket$$

2 Monodial Functor

2.1 Symmetric Monoidal Functor

Definition 3. A symmetric monoidal functor between SMCs $(\mathbb{C}, \bullet, 1, \alpha, \lambda, \rho, \gamma)$ and $(\mathbb{C}', \bullet', 1', \alpha', \lambda', \rho', \gamma')$ is a functor $F : \mathbb{C} \rightarrow \mathbb{C}'$ equipped with

1. A morphism $m_{1'} : 1' \rightarrow F1$.
2. For any two objects A and B in \mathbb{C} , a natural transformation $m_{A,B} : F(A) \bullet' F(B) \rightarrow F(A \bullet B)$

These must satisfy the following diagrams:

diagramshere

However in this particular case, assuming that $!$ is a symmetric monoidal (endo) functor means that $!$ comes equipped with a natural transformation

$$m_{A,B} : !A \otimes !B \rightarrow !(A \otimes B)$$

and a morphism

$$m_I : I \rightarrow !I$$

3 Monodial Adjunctions

4 Monodial Natural Transformations
