1	Monoidal Category	

## 1.1 Symmetric Monoidal Category

**Definition 1.** A symmetric monoidal catergory (SMC),  $(\mathbb{C}, \bullet, 1, \alpha, \lambda, \rho, \gamma)$ , is a category  $\mathbb{C}$  equippped with a bifunctor  $\bullet : \mathbb{C} \times \mathbb{C} \to \mathbb{C}$  with a neutral element 1 and natural isomorphisms  $\alpha, \lambda, \rho$ , and  $\gamma$ :

1. 
$$\alpha_{A,B,C}: A \bullet (B \bullet C) \xrightarrow{\sim} (A \bullet B) \bullet C$$

2. 
$$\lambda_A: 1 \bullet A \xrightarrow{\sim} A$$

3. 
$$\rho_A: A \bullet 1 \xrightarrow{\sim} A$$

4. 
$$\gamma_{A,B}: A \bullet B \xrightarrow{\sim} B \bullet A$$

which make the following 'coherence' diagrams commute.

The following equality is also require to hold:

$$\lambda_1 = \rho_1 : 1 \bullet 1 \to 1$$

#### 1.2 Symmetric Monoidal Closed Category

**Definition 2.** A symmetric monoidal closed category (SMCC),  $(\mathbb{C}, \bullet, \multimap, 1, \alpha, \lambda, \rho, \gamma)$ , is a SMC such that for all objects A in  $\mathbb{C}$ , the functor  $-\otimes A$  has a specified right adjoint  $A \multimap -$ .

Let  $\mathbb{C}$  be a SMC  $(\mathbb{C}, \bullet, 1, \alpha, \lambda, \rho, \gamma)$ . A structure, M, in  $\mathbb{C}$  for a given signature  $S_g$  is specified by giving an object  $\llbracket \sigma \rrbracket$  in  $\mathbb{C}$  for each type  $\sigma$ , and a morphism  $\llbracket f \rrbracket : \llbracket \sigma_1 \rrbracket \bullet \ldots \bullet \llbracket \sigma_n \rrbracket \to \llbracket \tau \rrbracket$  in  $\mathbb{C}$  for each function symbol  $f: \sigma_1, \ldots, \sigma_n \to \tau$ . In the case where n = 0 then the structure assigns a morphism  $\llbracket c \rrbracket : 1 \to \llbracket \tau \rrbracket$  to a constant  $c: \tau$ .

Given a context  $\Gamma = [x_1 : \sigma_1, ..., x_n : \sigma_n]$  we define  $\Gamma$  to be the product  $\sigma_1 \cdot ... \cdot \sigma_n$ . We represent the empty context with the neutral element 1. We need to define the bracketing convention. It shall be assumed that the tensor product is left associative, i.e.  $A_1 \cdot A_2 \cdot ... \cdot A_n$  will be taken to mean  $(...(A_1 \cdot A_2) \cdot ...) \cdot A_n$ . We find it useful to define two 'book-keeping' functions,

$$Split(\Gamma, \Delta) : \llbracket \Gamma, \Delta \rrbracket \to \llbracket \Gamma \rrbracket \bullet \llbracket \Delta \rrbracket$$

$$Split(\Gamma, \Delta) \stackrel{\text{def}}{=} \begin{cases} \lambda_{\Delta}^{-1} & \text{If $\Gamma$ empty} \\ \rho_{\Gamma}^{-1} & \text{If $\Delta$ empty} \\ id_{\Gamma \bullet A} & \text{If $\Delta = A$} \\ Split(\Gamma, \Delta') \bullet id_A; \alpha_{\Gamma, \Delta', A}^{-1} & \text{If $\Delta = \Delta'$, $A$} \end{cases}$$

$$Join(\Gamma, \Delta): \llbracket \Gamma, \Delta \rrbracket \to \llbracket \Gamma \rrbracket \bullet \llbracket \Delta \rrbracket$$

$$Join(\Gamma, \Delta) \stackrel{\text{def}}{=} \begin{cases} \lambda_{\Delta} & \textit{If $\Gamma$ empty} \\ \rho_{\Gamma} & \textit{If $\Delta$ empty} \\ id_{\Gamma \bullet A} & \textit{If $\Delta = A$} \\ \alpha_{\Gamma, \Delta', A}; Join(\Gamma, \Delta') \bullet id_{A} & \textit{If $\Delta = \Delta'$}, A \end{cases}$$

We shall also refer to indexed variants of these; for example

$$Split_n(\Gamma_1,...,\Gamma_n): \llbracket \Gamma_1,...,\Gamma_n \rrbracket \to \llbracket \Gamma_1 \rrbracket \bullet ... \bullet \llbracket \Gamma_n \rrbracket$$

which is defined in the obvious way.

The semantics of a term in context is then specified by a structural induction on the term.

$$[\![x:\sigma\rhd x:\sigma]\!]\ \stackrel{\mathrm{def}}{=}\ id_\sigma$$

$$\llbracket \Gamma_1,...,\Gamma_n \rhd f(M_1,...,M_n) : \tau \rrbracket \quad \stackrel{\mathsf{def}}{=} \quad Split_n(\Gamma_1,...,\Gamma_n); \llbracket \Gamma_1 \rhd M_1 : \sigma_1 \rrbracket \bullet ... \bullet \llbracket \Gamma_n \rhd M_1 : \sigma_n 0 \rrbracket ; \llbracket f \rrbracket$$

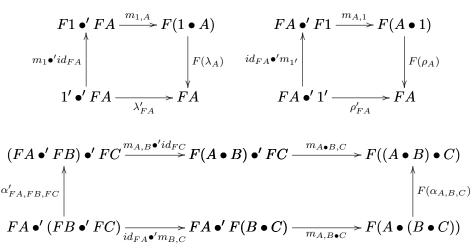

## 2 Monodial Functor

## 2.1 Symmetric Monoidal Functor

**Definition 3.** A symmetric monoidal functor between SMCs  $(\mathbb{C}, \bullet, 1, \alpha, \lambda, \rho, \gamma)$  and  $(\mathbb{C}', \bullet', 1', \alpha', \lambda', \rho', \gamma')$  is a functor  $F : \mathbb{C} \to \mathbb{C}'$  equipped with

- 1. A morphism  $m_{1'}: 1' \to F1$ .
- 2. For any two objects A and B in  $\mathbb{C}$ , a natural transformation  $m_{A,B}: F(A) \bullet' F(B) \to F(A \bullet B)$

These must satisfy the following diagrams:

$$FA \bullet' FB \xrightarrow{m_{A,B}} F(A \bullet B)$$

$$\gamma'_{A,B} \downarrow \qquad \qquad \downarrow^{F(\gamma_{A,B})}$$

$$FB \bullet' FA \longrightarrow F(B \bullet A)$$

However in this particular case, assuming that ! is a symmetrick monoidal (endo) functor means that ! comes equipped with a natural transformation

$$m_{A,B}: !A \otimes !B \rightarrow !(A \otimes B)$$

and a morphism

$$m_I:I\to !I$$
